

## FLAT ROOFS

### FLAT ROOFING

The sloping is made of light concrete using a brick row to separate the different surfaces. Over the light concrete, is extended a cement mortar coat to flatten its surface.

Over the cement mortar, a self-protected waterproof stickled sheet has been placed, which is added over the parapet and it is introduced into it through a hollow made on it. All of this is plastering with cement mortar. We can see how an expansion joint is built on the right brickwork parapet through extruded polystyrene panels with a sealed perimeter with a bituminous product.

Its upper finishing is built with a termination piece made of ceramic which lets the water flow out.

It is prepared to place a protection to the pavement if it would be necessary.
